IC PerMed Engagement Meeting, 10 June 2025

What is personalized medicine?

- Personalized medicine is an emerging practice of medicine that uses an individual's genetic profile, lifestyle and environment to guide decisions made about the prevention, diagnosis, and treatment of disease.
- Knowledge of a patient's genetic profile can help doctors select the proper medication or therapy and administer it using the proper dose or regimen.
- Personalized medicine is being advanced through data from the Human Genome Project.

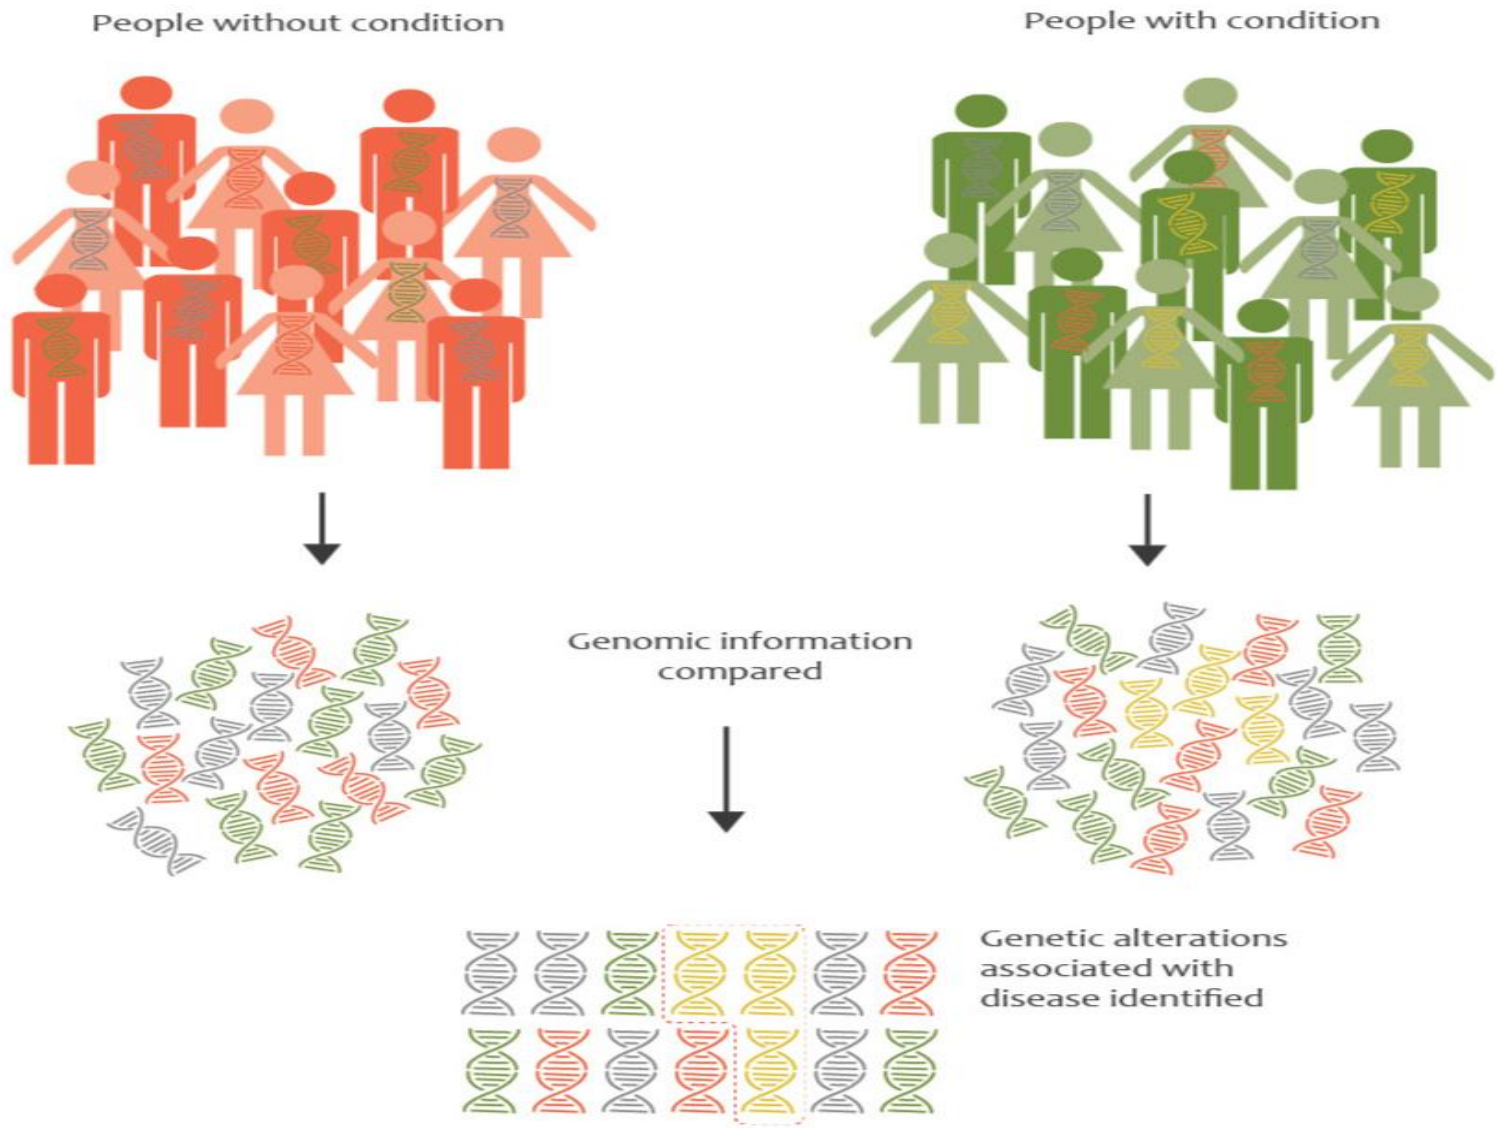
How researchers compare genomic information to identify genetic alterations



Genetic variation in the African population

1.4 billion people

Africa is the worlds second largest and second most populous continent

54 countries, >3000 ethnic groups, >2100 languages

~50% of the African population are children <18 years old

By 2050, 40% of the world's children will live in Africa

We used a deeply sequenced dataset of 910 individuals, all of African descent, to construct a set of DNA sequences that is present in these individuals but missing from the reference human genome. We aligned 1.19 trillion reads from the 910 individuals to the reference genome (GRCh38), collected all reads that failed to align, and assembled these reads into contiguous sequences (contigs). We then compared all contigs to one another to identify a set of unique sequences representing regions of the African pan-genome missing from the reference genome. Our analysis revealed 296,485,284 bp in 125,715 distinct contigs present in the populations of African descent, demonstrating that the African pan-genome contains ~10% more DNA than the current human reference genome. Although the functional significance of nearly all of this sequence is unknown, 387 of the novel contigs fall within 315 distinct protein-coding genes, and the rest appear to be intergenic.

Since its initial publication[1,2], the human genome sequence has undergone continual improvements aimed at filling gaps and correcting errors. The latest release, GRCh38, spans 3.1 gigabases (Gb), with just 875 remaining gaps[3]. The ongoing effort to improve the human reference genome, led by the Genome Reference Consortium, has in recent years added alternate loci for genomic regions where variation cannot be captured by SNPs or small insertions and deletions (indels). These alternate loci, which comprise 261 scaffolds in GRCh38, capture a small amount of population variation and improve read mapping for some data sets.

Despite these efforts, the current human reference genome derives primarily from a single individual[4], thus limiting its usefulness for genetic studies, especially among admixed populations, such as those representing the African diaspora. In recent years, a growing number of researchers have emphasized the importance of capturing and representing sequencing data from diverse populations and incorporating these data into the reference genome

The African continent is regarded as the cradle of modern humans and African genomes contain more genetic variation than those from any other continent, yet only a fraction of the genetic diversity among African individuals has been surveyed[1]. Here we performed whole-genome sequencing analyses of 426 individuals—comprising 50 ethnolinguistic groups, including previously unsampled populations—to explore the breadth of genomic diversity across Africa. We uncovered more than 3 million previously undescribed variants, most of which were found among individuals from newly sampled ethnolinguistic groups, as well as 62 previously unreported loci that are under strong selection, which were predominantly found in genes that are involved in viral immunity, DNA repair and metabolism. We observed complex patterns of ancestral admixture and putative-damaging and novel variation, both within and between populations, alongside evidence that Zambia was a likely intermediate site along the routes of expansion of Bantu-speaking populations. Pathogenic variants in genes that are currently characterized as medically relevant were uncommon—but in other genes, variants denoted as 'likely pathogenic' in the ClinVar database were commonly observed. Collectively, these findings refine our current understanding of continental migration, identify gene flow and the response to human disease as strong drivers of genome-level population variation, and underscore the scientific imperative for a broader characterization of the genomic diversity of African individuals to understand human ancestry and improve health.

What Did We (Africans) Learn Post HGV Project?

- Importance of genotyping
- Importance of phenotyping
- Road towards precision medicine

Diagnostics

Benign Variants Misclassified as Pathogenic in Genetic Reports

Seven patients, all of African or unspecified ancestry, received reports between 2005 and 2007 that they had one of two variants, *TNNI3* P82S or *MYBPC3* G278E, that were classified as "pathogenic" or "presumed pathogenic" (Table 1); these variants were later reclassified as benign. In five of the seven reports, P82S or G278E was the most pathogenic variant reported to the patient. Six additional patients with inconclusive or positive genetic-testing results that were reported later were listed as having one of these two variants, which were characterized as being of "unknown significance" or "pathogenicity debated." Among the 13 patients, 9 had a clinical diagnosis of hypertrophic cardiomyopathy, 2 had clinical features of hypertrophic cardiomyopathy, and 1 had clinical symptoms of hypertrophic cardiomyopathy. Five of the 13 patients had a documented family history of hypertrophic cardiomyopathy. From the records available, it was not possible to determine whether the families affected by the reclassification of these variants were recontacted.

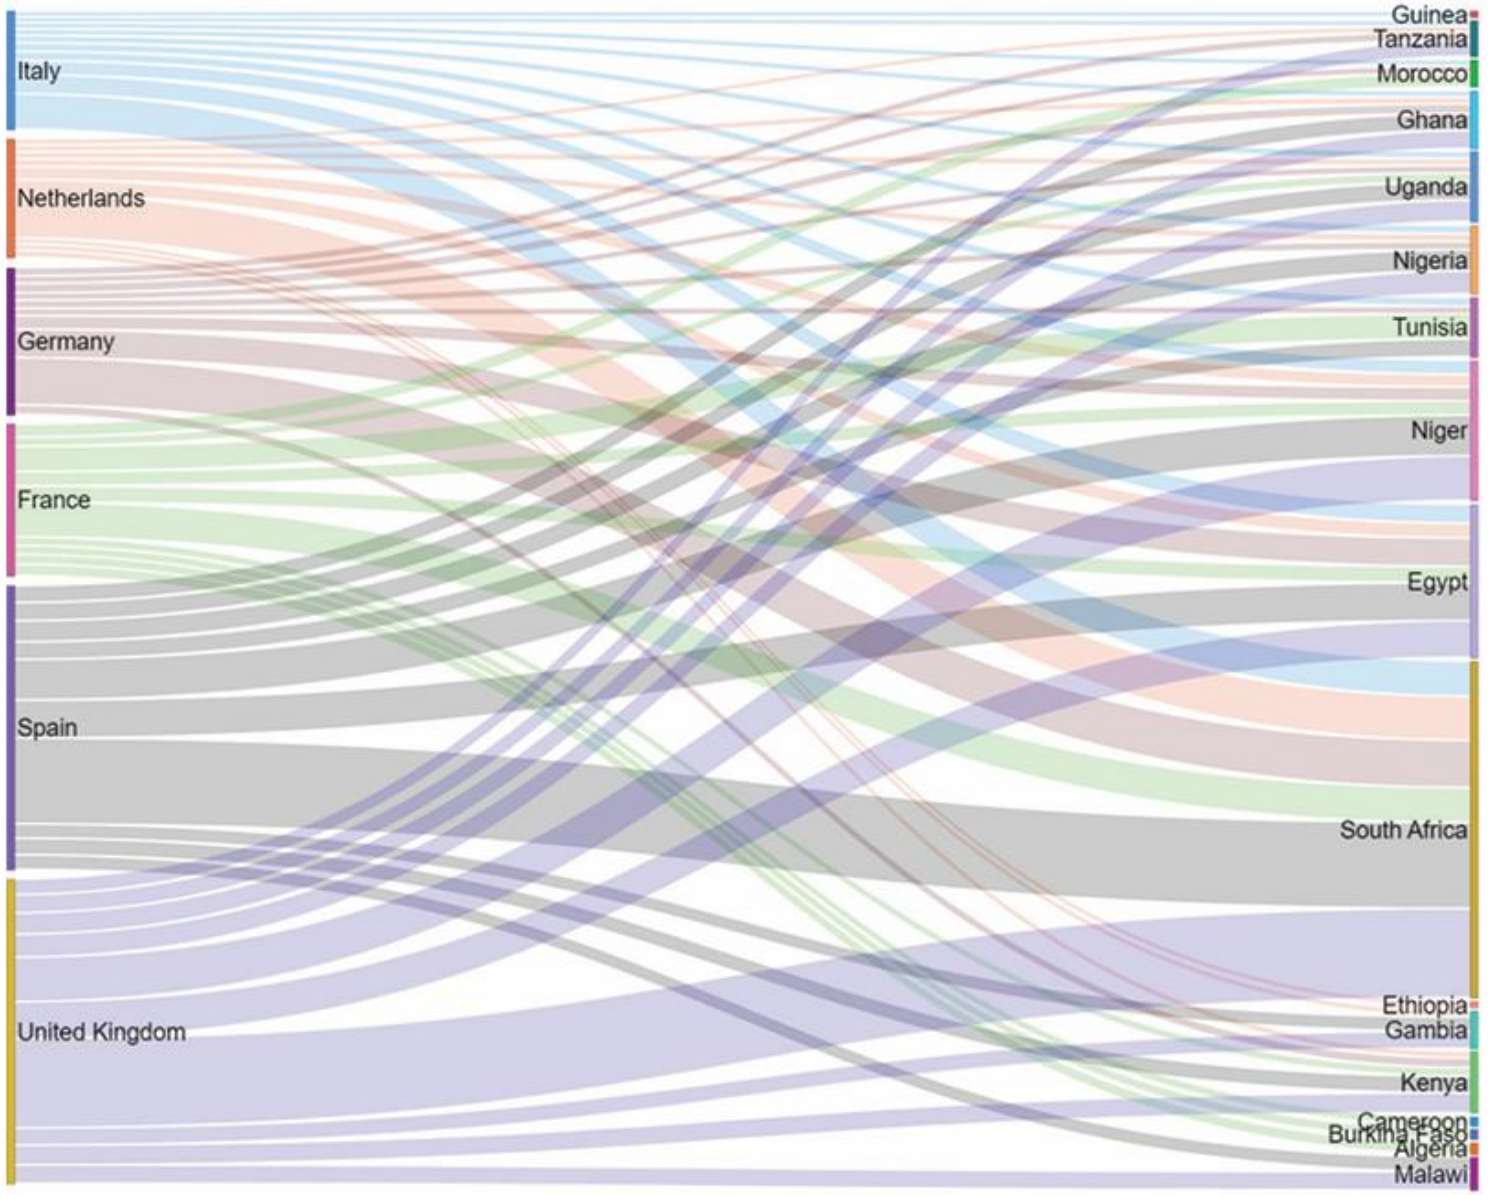
Pressing issues in Africa

1. Building research capacity for infectious genomic research
2. Improving medical genetics and services
3. Setting up genetic testing for congenital diseases
4. Cytogenetic techniques as diagnostic tools – routine
5. Ethical considerations in genomics in Africa
6. Bio banking for genomic studies in Africa – socio-cultural issues
7. Standardized bio repositories : Resource for High quality samples in resource limited setting
8. Bioinformatics training challenges
9. Pharmacogenomics in Africa – challenges
10. Genetic syndromes in diverse populations - limitations

Co-authorship network between the highly active European countries (United Kingdom, France, Germany, Italy, Spain and the Netherlands) with their top African collaborating countries



EU-Africa PerMed

Action Plan to facilitate, foster and promote Personalised Medicine research collaboration between Europe and Africa

EU Africa PerMed has received funding from the European Union's Horizon 2020 Research and Innovation programme under grant agreement No 964333

Context of the Action plan

Key Objectives:	Facilitate collaboration in PM research.	Strengthen Africa-Europe bilateral STI relations.	**Core Features:**
Infrastructure development: Biobanks, genomic hubs.	Capacity building: Training, knowledge transfer.	Ethical and regulatory frameworks: FAIR principles and inclusivity.	**Why It Matters for Africa:**
	Provides tools to address local healthcare challenges.	Aims to build Africa's PM capacity and integrate it into healthcare systems.	

Strengths of the action plan

Infrastructure Development:
Biobanks and genomic hubs to address Africa’s research infrastructure gaps.
Enhanced bioinformatics networks for data analysis.
Capacity Building:
Focus on training and knowledge exchange to create skilled professionals.
Ethics and Governance:
Emphasis on FAIR principles, ethical data sharing, and regulatory frameworks.
Inclusivity:
Acknowledges the need for African representation in global research.

Challenges from an African perspective

- **Infrastructure Gaps:**
- Limited access to advanced research facilities.
- Reliance on external resources.
- **Sustainability Concerns:**
- Long-term funding and government buy-in.
- **Equity in Collaboration:**
- Risks of "helicopter science" and unequal partnerships.
- **Policy Gaps:**
- Lack of integration of PM into national health systems.

Opportunities for mutual benefit

- **Africa's Genetic Diversity:**
- Unparalleled opportunities for global genomic discoveries.
- **Knowledge Transfer:**
- European expertise in PM can strengthen Africa's research capacity.
- **Health Equity:**
- Collaborative projects can reduce health disparities and improve outcomes.

Actionable steps to implement the plan's recommendations

1

Promote African-Led Initiatives:

- Encourage African leadership in research and decision-making.

2

Tailor PM Strategies:

- Adapt solutions to Africa's socio-economic and cultural contexts.

3

Secure Long-Term Funding:

- Combine local and international funding sources.

4

Expand Training Programs:

- Include scientists, healthcare workers, and policymakers.

5

Leverage Existing Networks:

- Build on initiatives like H3Africa.

Health Economics of Personalised Medicine: Summary Table

- Every $1 invested in the Human Genome Project generated an estimated $141 in economic output.

Category	Key Statistic / Insight	Reference
Reduction in treatment cost	67% of psychiatric patients experienced overall cost reduction after pharmacogenomic intervention	Rinser, 2023 – LinkedIn article
Drug development savings	PM could lower drug development costs by ~17%, saving up to **$26 billion annually**	Sanogenetics blog
Oncology cost impact	Global implementation of PM in cancer could save **>$100 billion/year** by avoiding ineffective treatment	Socio-economics of PM in Asia (Routledge)
Cost-effectiveness baseline	Most PM interventions evaluated were cost-effective compared to standard care	Kewal K. Jain., 2009 – Springer Chapter

Africa's people must be able to write their own genomics agenda

Genomics on the continent is finally getting the attention it deserves – but funding needs to come from more diverse sources.
